

Create Business Insights for real-world Data

For this task, I worked on an FMCG sales dataset from 2022 to 2024. The dataset includes details like product, category, region, price, units sold, and delivery time. The objective was to understand sales performance and generate useful business insights.

First, I loaded data in Python then performed basic operations on it. There were no duplicates and missing values found. Since there was no sales column, I created one by multiplying units sold with price per unit. Then, I performed analysis using different plots.

The analysis showed that a few products generate most of the revenue. **Yogurt** is the top-performing **category**, while some categories like **Juice** have **lower sales**. **Sales** also **vary** across **regions**. Promotions were found to increase sales, which shows their importance in boosting demand.

I also used SQL to analyse the data, including sales by category, region, and monthly trends. Due to import issues, the SQL analysis was performed on **182,931 rows**.

Then, I created an dashboard in Power BI with KPIs and charts. I also added slicers (filters) for category, region, and channel. These slicers help to filter the data easily and view specific insights, making the dashboard more interactive.

After the analysing , to increase the sales , business should focus on high-performing products and categories while improving weaker areas to increase total sales.
